

Unit Testing

Course Software Testing & Verification

2025/26

Wishnu Prasetya & Paige North

Plan

- What is unit testing, and why we do it?
- Some essentials on unit testing:
 - Unit testing in C#
 - Specifying (and testing) with pre- and post-conditions
 - Other types of specifications: classinv, ADT, FSM.
 - Mocking

Note: The subject of unit testing is only glossed over in A&O. Since unit testing plays an important role in software engineering nowadays, in this lecture we will spend a bit more time to discuss it.

What is “testing” ?

Testing a program: verifying the correctness (or other qualities) of the program by inspecting a **finite number** of executions.

As such, testing is a **pragmatic** approach of verification (and we have to accept that it is inherently **incomplete**).

Note: we will discuss a more complete approach in the 2nd half of the course.

Example: determining triangle type

Equilateral

Isosceles

Scalene

```
TriangleType TriType(Float a, Float b, Float c) { ... }
```

If a , b , c represent the sides of a triangle, this method determines the type of the triangle.

An example of a test

What is a “test” ?

```
Test1() { ty = TriType(4,4,1) ; Assert.AreEqual(Isosceles,ty) }
```

- A “test” (also called *test-case*) for a program $P(x)$ specifies an input for $P(x)$ and the output it expects.
- The definition fits nicely for a function/method-like P .
 - What if P is an interactive program e.g. a web application?
 - What if P is a continuously running system, e.g. a car control system?

A more general definition

*A **test** for $P(x)$ specifies a sequence of interactions along with the needed parameters on P , and the expected responses P should produce.*

- Compare this with AO Def. 1.17 (both definitions try to say the same thing).

Multi-level testing

Simplified version of AO Fig. 1.2.

The diagram above is often called the V-model of multi-level testing. In practice people do testing in multi level.

Unit Testing

Make sure that your units are correct!

- Invest in unit testing! Debugging an error at the system-test level is much more costly than at the unit level.
- Note: so-called “unit testing tool” can often also be used to facilitate integration and system testing.

What is a “unit” ?

- Program “units” should not be too large, that you can still easily comprehend of its logic.
- Possibilities: functions, methods , or classes as units.

What is a “unit” ?

- **However**, different types of units may have different types of interactions and complexity, thus requiring different approaches to test them:
 - a *function*’s behavior depends only on its parameters; does **not** have any side effect.
 - A *procedure* depends-on its parameters, but may additionally have side effect on its parameters.
 - A *method* may additionally depend on and affect instance variables, or even class (static) variables.
 - A *class*: is a collection of potentially interacting methods.

Unit testing in C#

- Unit Testing Framework: MSUnit, **NUnit**, xUnit. We will be using **NUnit**.
- Coverage tool: both Rider and VS Enterprise have it.
- **Check related tutorials/docs:**
 - NUnit Quick Start (older version, but will do for a tutorial):
<https://nunit.org/docs/2.5.9/quickStart.html>
 - NUnit doc: <https://github.com/nunit/docs/wiki/NUnit-Documentation>
 - Testing from your IDE (Rider):
 - <https://www.jetbrains.com/help/rider/Introduction.html>, check the entry on “Get Started with Unit Testing”.
 - Obtaining test coverage information:
https://www.jetbrains.com/help/dotcover/Getting_Started_with_dotCover.html
- In this lecture we focus on the underlying concepts.

The structure of a solution with “test projects”

A *test project* is just a project in your solution that contains your *test-classes*.

dependencies

The structure of a “test project”

- A solution may contain multiple projects; including multiple test projects.
- A test project is used to group related *test classes*. You decide what “related” means; e.g. you may decide to put all test-cases for package/namespace in its own test project.
- A test class is used to group related *test methods*.
- A test method does the actual testing work, it usually encodes a single test-case.

Test Class and Test Method (NUnit)

```
[TestFixture]
public class TriangleTest {
    [SetUp]
    public void Init() ...
    //[TearDown]
    //public void Cleanup() ...
}
```

```
[Test]
public void Test1_Triangle() ...
```

```
[Test]
public void Test2_Triangle() ....
```

```
}
```

```
Test1_Triangle() {
    var ty = TriType(4,4,1) ;
    Assert.AreEqual(Isosceles, ty)
}
```

Inspecting Test Result (Rider)

The screenshot displays the Rider IDE's Unit Tests window. The left pane shows a tree view of test results: MSUnitTests (2 tests) Success, NUnitTests (232 tests) Failed: 1 test failed, and NUnitTestClass1 (22 tests) Failed: 1 test failed. The right pane shows the details of the failed test: fullCombinatoricTest_execeptionCase_Creature_contr(-1,-1) [84 ms] Expected: NUnitTests.NUnitTestClass1. The error message states: Expected: <System.DivideByZeroException> But was: <System.ArgumentException: Value does not fall within the expected range.> at STVroque.GameLogic.Creature..ctor(String id, Int32 hp, Int32 ar) in /Users/iswbprasetya/workshop/projects/STVroque/csharp/STVroque/STVroque/GameLogic/Creature.cs:line 26 at NUnitTests.NUnitTestClass1.<c__DisplayClass2_0.>.fullCombinatoricTest_execeptionCase_Creature_contr(b__0()) in /Users/iswbprasetya/workshop/projects/STVroque/csharp/STVroque/STVroque/GameLogic/Creature.cs:line 26. The bottom status bar shows various toolbars including TODO, NuGet, Unit Tests, Performance Profiler, Terminal, Repository, Build, and Event Log.

Unit Tests: Explorer All tests from <MSUnitTests> x

NUnitTests	99%	1/125
SomeClassToTest	97%	1/32
Expr(int,int)	89%	1/9
Expr(int,int)	100%	0/12

Finding the source of an error: use a debugger!

- Add break points; execution is stopped at every BP.
- You can inspect the values of every variable
- You can proceed to the next BP, or execute one step at a time: step-into, step-over, step-out.

Test Oracle

```
Test1_Triangle() {  
    var ty = TriType(4,4,1) ;  
    Assert.AreEqual(Isosceles, ty)  
}
```

An oracle specifies your expectation on the program's responses.

- Check NUnit doc on Assertions:
<https://github.com/nunit/docs/wiki/Assertions>
 - Classic way: `Assert.IsTrue(x == 0)` or `Assert.AreEqual(0,x)`
 - Constraint model: `Assert.That(x, Is.EqualTo(0))`

A test needs oracles

```
Test1_Triangle() {  
    var ty = TriType(4,4,1) ;  
    Assert.AreEqual(Isosceles, ty)  
}
```

- How do we determine what the expected responses of the program under test?
- Ideally, there exists a specification (or you have to elicit that, somehow).

Informal or formal specification?

```
TriType(Float a, Float b, Float c) { ... }
```

Informal: *“If a , b , c represent the sides of a triangle, this method determines the type of the triangle.”*

Formal specification, pros and cons

- Pros:
 - Precise
 - Can be turned to “executable” specifications.
 - When the program is changed, only its specification needs to be adapted; we don’t have to re-program the test cases.
 - Allow you to **“generate”** the test sequences/inputs rather than writing them manually.
- Cons:
 - Capturing the intended specification is not always easy.
 - Additional work.

Example

- Formalize the specification of $\text{TriType}(a,b,c)$.

Informal: *“If a, b, c represent the sides of a triangle, this method determines the type of the triangle.”*

Formalizing specification with a pre- and post-conditions (in Pred. Logic)

Pre-condition

$$\{ a > 0 \wedge b > 0 \wedge c > 0 \wedge a + b > c \wedge a + c > b \wedge b + c > a \}$$

TriType(a,b,c)

$$\begin{aligned} &\{ (a=b \wedge b=c \wedge a=c) \Leftrightarrow \text{retval}=\text{Equilateral} \\ &\quad \wedge \\ &\quad (a \neq b \wedge b \neq c \wedge a \neq c) \Leftrightarrow \text{retval}=\text{Scalene} \\ &\quad \wedge \\ &\quad \dots \Leftrightarrow \text{retval}=\text{Isosceles} \} \end{aligned}$$

Post-condition

- Formal, but not yet “executable”. We can’t invoke it from our test cases.
- “...” above means “information not shown” (it does not mean “else”)

Turning it to an in-code specification

(here, encoded as a parameterized NUnit-test)

```
void MethodSpec(x) {
```

```
    if (...pre-cond...) {
```

Pre-condition

```
        var retval = Method(x)
```

```
        Assert.IsTrue( ...post cond... )
```

Post-condition

```
    }  
    else Assert.Throws<expected exception>(() => Method(x));
```

```
}
```

Check that the method throws the right exception when the pre-cond is violated.

In-code specifications are specifications expressed in a **programming language**.

It is less clean, but it is **executable**, so you can invoke them from your tests.

In-code Spec of TriType

(encoded as a parameterized NUnit-test)

```
bool TriTypeSpec(float a, float b, float c) {
```

Pre-condition

```
    if (a>0 && b>0 && c>0 && ...) {
```

```
        var retval = TriType(a,b,c)
```

Post-condition

```
        Assert.True((retval == Equilateral) == (a==b && b==c && a==c))
```

```
        Assert.True((retval == Scalene) == (a!=b && b!=c && a!=c))
```

```
        Assert.True((retval == Isosceles) == ...)
```

```
    }
```

```
    else Assert.Throws<ArgumentException>(() => TriType(a,b,c))
```

```
}
```

In-code Spec v2 of TriType

(encoded as a parameterized NUnit-test)

```
bool TriTypeSpec(float a, float b, float c) {
```

Pre-condition

```
Assume(a>0 && b>0 && c>0 && ...) ;
```

```
var retval = TriType(a,b,c)
```

Post-condition

```
Assert.True((retval == Equilateral) == (a==b && b==c && a==c))
```

```
Assert.True((retval == Scalene) == (a!=b && b!=c && a!=c))
```

```
Assert.True((retval == Isosceles) == ...)
```

```
}
```

v1 (previous slide) : if the method under test commits to checking the pre-cond and is expected to throw a specific exception when the pre-cond is violated.

v2 : if the method under test does check the pre-cond (shifting the responsibility to the caller). The Assume-construct of NUnit serves for filtering the test-input to let through only those that satisfy the assumed condition.

Now you can write your tests like this

(NUnit, parameterized test)

```
[TestCase(4,4,1)]  
[TestCase(4,4,4)]  
[TestCase(1,2,4)]  
[TestCase(0,4,1)]  
[TestCase(0,0,0)]  
...  
bool TriTypeSpec(float a, float b, float c) { ... }
```

Important observation: this approach also opens a way for you to “**generate**” the tests, e.g. using a QuickCheck-like tool.

Note: “TestCase” NUnit attribute can only handle simple types. See also the doc. for ‘**TestCaseSource**’ NUnit attribute.

Example2: specification for a method on array/collection

```
int GetIndex(x, int[ ] a) { ... }
```

Informal: *given a non-empty integer array a, and assume x occurs in a, the method returns an index k in a of an x.*

Formal spec: now we also need “quantifiers”

- **Informal:** *given a non-empty integer array a , and assume x occurs in a , the method returns an index k in a of an x .*

$$\{ a \neq \text{null} \wedge (\exists k: 0 \leq k < a.\text{length} : a[k]=x) \}$$

GetIndex(x , $\text{int}[] a$)

$$\{ 0 \leq \text{retval} < a.\text{length} \wedge a[\text{retval}] = x \}$$

Providing quantifiers as in-code

- Define (static):

```
Exists<T> ( T [ ] a, Predicate<int> P) {  
    for (int k=0; k<a.Length; k++) if (P(k)) return true ;  
    return false ;  
}
```

- **Exists**(a,P) = there exists a valid index i of a, such that P(i) is true.
- Similarly you can define **Forall**(a,P).
- Similarly you can define quantifiers for collections.
- Already provided in STVRogue project.

Specifying properties of arrays (and similarly collections)

- Now we can write in-code properties, e.g. : the array `a` contains only positive integers:

Forall(`a`, `k => a[k] > 0`)

- Or, the array `a` has at least one positive integers:

Exists(`a`, `k => a[k] > 0`)

- Alternatively using built-in `a.Any(..)` and `a.All(..)`

Example: in-code spec of GetIndex

Informal: *given a non-empty integer array a, and assume x occurs in a, the method returns an index k in a of an x.*

```
GetIndexSpec(int x, params int[] a) {
```

```
    if (a!=null && Exists(a, k => a[k]==x)) {
```

Pre-condition

```
        var retval = GetIndex(x,a)
```

```
        Assert.IsTrue(a[retval] == x) }
```

Post-condition

```
    else Assert.Throws<ArgumentException>(() => GetIndex(x,a))
```

```
}
```

Using GetIndexSpec for parameterized test

```
[TestCase(0)]  
[TestCase(0,1)]  
[TestCase(0,0,0)]  
[TestCase(0,1,1,1,0)]  
...  
GetIndexSpec(int x, params int[] a) { ... }
```

Specifying a “class”

- Many classes have methods that *interact with each other* (e.g. as in Stack). How to specify (and test) these interactions?
- Option-1: specify every method with pre- and post-conditions (we discussed this).
 - This is expressive enough, though pre- and post-conditions may not, arguably, naturally capture inter-method interactions.
 - May need to access private fields. Also, directly testing private methods via their pre-/post is an issue.

Specifying a “class”

- Other options, which can be user either as alternatives or in conjunction with pre/post-conditions:
 - class invariant
 - Abstract Data Type (ADT)

Specifying with class invariant

```
class Thermometer {  
    double temperature // in Celcius  
    Value()  
    Incr(t)  
    Decr(t)  
}
```

A **class invariant** of a class C specifies valid states of instances of C. When an instance is created, it must have a valid state. All operations/methods of C are expected to restore the state of their target instance to a valid state.

Example: **class inv** for Thermometer: temperature ≥ -273.15

Specifying a class as an ADT

An Abstract Data Type (ADT) is a model of a (stateful) data structure. The data structure is modeled abstractly by only describing a set of *operations* (without exposing underlying data structure implementing the state).

The semantic is described in terms of “logical properties” (also called the ADT’s *axioms*) over those operations.

ADT specification for Thermometer

```
class Thermometer {  
    double temperature // in Celcius  
    Value()  
    Incr(t)  
    Decr(t)  
}
```

Axioms:

1. For any t_0 and $t > 0$: after $\text{Incr}(t)$, $\text{Value}()$ should be $t_0 + t$, if t_0 was $\text{Value}()$ before.
2. For any t_0 and $t > 0$: after $\text{Decr}(t)$, $\text{Value}()$ should be $\max(t_0 - t, -273.15)$, if t_0 was $\text{Value}()$ before.

Notice that the ADT axioms never refer to the class state variables.

Testing ADT

Testing an ADT amounts to verifying each of its axioms, each can be formulated as a **parameterized test**.

For example, to test Thermometer's Axiom-1:

```
Axiom1(Thermometer s, double t) {  
    assumeThat(t > 0) ;  
    t0=s.Value() ; s.Incr(t) ; assertEquals(t0+t, s.Value()) ; }
```

We can imagine e.g. these test cases :

1. s such that s.temperature is -273.15 and s such that s.temperature > -273.15
2. very small t and normally large t

Example-2 : specifying my ItemStore

```
class ItemStore<T> {  
    Put(T x)  
    T Get()  
    int Size()  
}
```

Axioms :

1. The Size of a new ItemStore is 0.
2. After Put(x), Size is 1 + the Size before.
3. If Size>0, after Get(), Size is the Size before - 1.
4. After Put(x), followed by n-times Put(.) and Get(), such that k-th Get is preceded by at least k-times Put, Get() gives x.

Do these look familiar?

Testing ADT

For example, to test Ax-4:

```
Axiom4(ItemStore s, T x, T y) {  
    s.Put(x) ; s.Put(y) ; s.Get() ; assertEquals(x, s.Get()) ; }
```

We can imagine e.g. these test cases :

1. empty s
2. a non-empty s that does not contain x
3. an s that already contains x

Mock

- Consider testing a class C that uses a class D.
- In a larger project, it is possible that D is developed by a separate team, and by the time you want to test C, D is not ready/stable yet. **Solution:** we "mock" D.
- A mock of a program P:
 - has the same interface as P
 - may only implement a very small subset of P's behavior
 - fully under your control
- You would want a way to conveniently create mocks.
- Mentioned in Ch. 6.2.1 A&O (12.2.1 2nd Ed).

Example: Heater

class Heater

```
double limit
bool active
Thermometer thermometer
public AutoOff() {
    // if thermometer.value()
    // exceeds the limit,
    // deactivate the heater }
```

class Thermometer

```
double Value()
...
```

Notice that for this
test you need a
working Thermometer
class.

```
test1() {
    thermometer = ... // get some thermometer
    Heater heater = new Heater(thermometer)
    Assume.That(thermometer.Value() >= heater.limit+0.001)
    heater.AutoOff()
    Assert.IsFalse(heater.active)
}
```

You need to restructure a bit

class Heater

```
double limit  
bool active  
IThermometer thermometer  
Heater(IThermometer t) // contr  
autoOff() {  
    // if thermometer.value()  
    // exceeds the limit,  
    // deactivate the heater  
}
```

```
interface IThermometer  
double Value()  
...
```

```
class Thermometer
```

To facilitate mocking usually you need to replace your dependency so that your class of interest depends on interfaces instead.

Creating mocks dynamically using NSubstitute

- Create an instance of an Interface, by calling the method “For” from the class “ NSubstitute.Substitute” :

```
thermometer = Substitute.For<IThermometer>()
```

- You can program the behavior of the interface’s methods on-demand. General form: mock.<method>(x1,x2,...).**Returns**(y), e.g.:

```
thermometer.Value ().Returns(100)
```

Now whenever you do thermometer.Value() this will return 100.

Test with a mock

class Heater

double limit

bool active

IThermometer thermometer

Heater(IThermometer t)

autoOff()

interface IThermometer

double Value()

...

Now we can write test1() like this:

```
test1() {
```

```
    thermometer = Substitute.For<IThermometer>()
```

```
    Heater H = new Heater(thermometer)
```

```
    thermometer.Value().Returns(heater.limit + 0.001)
```

```
    H.autoOff()
```

```
    Assert.IsFalse(H.active)
```

```
}
```

Creating a mock thermometer and programming its behavior.
